

Chapter 3: Abstract Data Type (ADT) and Object-Oriented Programming (OOP)

3.2 Designing Specification

设计规约

March 12, 2020

Objective of this lecture

- Understand preconditions and postconditions in method specifications, and be able to write correct specifications (方法的规约)
- What preconditions and postconditions are, and what they mean for the implementor and the client of a method (前置/后置条件)
- Understand underdetermined specs, and be able to identify and assess nondeterminism (欠定规约、非确定规约)
- Understand declarative vs. operational specs, and be able to write declarative specs (陈述式、操作式规约)
- Understand strength of preconditions, postconditions, and specs; and be able to compare spec strength (规约的强度及其比较)
- Be able to write coherent, useful specifications of appropriate strength (如何写出好的规约)

Outline

1. **Function / method in programming language**
2. **Specification: Programming for communication**
 - Why specification is needed
 - Behavioral equivalence
 - Specification structure: pre-condition and post-condition
 - Testing and verifying specifications
3. **Designing specifications**
 - Classifying specifications
 - Diagramming specifications
 - Quality of a specification
4. **Summary**

上一节关注了编程语言中的“数据类型”、“变量”、“值”，尤其是mutable和immutable的类型/值/引用

本节转向“方法/函数/操作”如何定义——编程中的“动词”、规约

Reading

- MIT 6.031: 06、07
- CMU 17-214: Sep 05

1 Functions & methods in programming languages

Parameters

```
[...] NAME (TYPE NAME, TYPE NAME) {  
    STATEMENTS  
}
```

To call:

```
NAME(arg1, arg2);
```

- **Attention:** parameter type mismatch when calling a method – **static checking** 参数类型是否匹配，在静态类型检查阶段完成

Return Values

```
public static TYPE NAME() {  
    STATEMENTS;  
    return EXPRESSION;  
}
```

`void` means “no type”

返回值类型是否匹配，也在静态类型检查阶段完成

Methods: Building Blocks

- Big programs are built out of small methods
- Methods can be individually developed, tested and reused
- User of method does not need to know how it works --- this is called “**abstraction**”

“方法”是程序的“积木”，可以被独立开发、测试、复用
使用“方法”的客户端，无需了解方法内部具体如何工作 — “抽象”

A complete method

```
public class Hailstone {
```

```
    /**
```

```
     * Compute a hailstone sequence.
```

```
     * @param n Starting number for sequence. Assumes  $n > 0$ .
```

```
     * @return hailstone sequence starting with n and ending with 1.
```

```
     */
```

```
    public static List<Integer> hailstoneSequence(int n) {
```

```
        List<Integer> list = new ArrayList<Integer>();
```

```
        while (n != 1) {
```

```
            list.add(n);
```

```
            if (n % 2 == 0) {
```

```
                n = n / 2;
```

```
            } else {
```

```
                n = 3 * n + 1;
```

```
            }
```

```
        }
```

```
        list.add(n);
```

```
        return list;
```

```
    }
```

```
}
```

方法的规约spec

方法的实现体implementation

2 Specification: Programming for communication

(1) Documenting in programming

Java API documentation: an example

java.util

Class `LinkedList<E>`

java.lang.Object

java.util.AbstractCollection<E>

java.util.AbstractList<E>

java.util.AbstractSequentialList<E>

java.util.LinkedList<E>

Type Parameters:

E - the type of elements held in this collection

All Implemented Interfaces:

Serializable, Cloneable, Iterable<E>, Collection<E>, Deque<E>, List<E>, Queue<E>

```
public class LinkedList<E>
  extends AbstractSequentialList<E>
  implements List<E>, Deque<E>, Cloneable, Serializable
```

Doubly-linked list implementation of the `List` and `Deque` interfaces. Implements all optional list operations, and permits all elements (including `null`).

All of the operations perform as could be expected for a doubly-linked list. Operations that index into the list will traverse the list from the beginning or the end, whichever is closer to the specified index.

Note that this implementation is not synchronized. If multiple threads access a linked list concurrently, and at least one of the threads modifies the list structurally, it *must* be synchronized externally. (A structural modification is any operation that adds or deletes one or more elements; merely setting the value of an element is not a structural modification.) This is typically accomplished by synchronizing on some object that naturally encapsulates the list. If no such object exists, the list should be "wrapped" using the `Collections.synchronizedList` method. This is best done at creation time, to prevent accidental unsynchronized access to the list:

```
List list = Collections.synchronizedList(new LinkedList(...));
```

The iterators returned by this class's `iterator` and `listIterator` methods are *fail-fast*: if the list is structurally modified at any time after the iterator is created, in any way except through the iterator's own `remove` or `add` methods, the iterator will throw a `ConcurrentModificationException`. Thus, in the face of concurrent modification, the iterator fails quickly and cleanly, rather than risking arbitrary, non-deterministic behavior at an undetermined time in the future.

Note that the fail-fast behavior of an iterator cannot be guaranteed as it is, generally speaking, impossible to make any hard guarantees in the presence of unsynchronized concurrent modification. Fail-fast iterators throw `ConcurrentModificationException` on a best-effort basis. Therefore, it would be wrong to write a program that depended on this exception for its correctness: *the fail-fast behavior of iterators should be used only to detect bugs*.

This class is a member of the Java Collections Framework.

Since:

1.2

Java API documentation: an example

Field Summary

Fields inherited from class java.util.AbstractList

modCount

Constructor Summary

Constructors

Constructor and Description

LinkedList()

Constructs an empty list.

LinkedList(Collection<? extends E> c)

Constructs a list containing the elements of the specified

Constructor Detail

LinkedList

public **LinkedList()**

Constructs an empty list.

LinkedList

public **LinkedList(Collection<? extends E> c)**

Constructs a list containing the elements of the specified collection, in the order they are returned by the collection's iterator.

Parameters:

c - the collection whose elements are to be placed into this list

Throws:

NullPointerException - if the specified collection is null

Method Summary

Methods

Modifier and Type	Method and Description
boolean	add(E e) Appends the specified element to the end of this list.
void	add(int index, E element) Inserts the specified element at the specified position in this list.
boolean	addAll(Collection<? extends E> c) Appends all of the elements in the specified collection to the end of this list, using the specified iterator.
boolean	addAll(int index, Collection<? extends E> c) Inserts all of the elements in the specified collection into this list at the specified position.
void	addFirst(E e) Inserts the specified element at the beginning of this list.
void	addLast(E e) Appends the specified element to the end of this list.
void	clear() Removes all of the elements from this list.
Object	clone() Returns a shallow copy of this <code>LinkedList</code> instance.
boolean	contains(Object o) Returns <code>true</code> if this list contains the specified element.

indexOf

public **int** **indexOf(Object o)**

Returns the index of the first occurrence of the specified element in this list, or -1 if this list does not contain the element. More formally, returns the lowest index *i* such that `(o==null ? get(i)==null : o.equals(get(i)))`, or -1 if there is no such index.

Specified by:

`indexOf` in interface `List<E>`

Overrides:

`indexOf` in class `AbstractList<E>`

Parameters:

o - element to search for

Returns:

the index of the first occurrence of the specified element in this list, or -1 if this list does not contain the element

Documenting Assumptions

- Writing the type of a variable down documents an assumption about it: e.g., this variable will always refer to an integer. 变量的数据类型定义
 - Java actually checks this assumption at compile time, and guarantees that there's no place in your program where you violated this assumption.
- Declaring a variable `final` is also a form of documentation, a claim that the variable will never change after its initial assignment. `final`关键字定义了设计决策：“不可改变”
 - Java checks that too, statically.
- How about the assumptions of functions / methods?
- 代码本身就蕴含着你的设计决策，但是远远不够

Programming for communication

- **Why do we need to write down our assumptions?**
 - Because programming is full of them, and if we don't write them down, we won't remember them, and other people who need to read or change our programs later won't know them. They'll have to guess.
 - 为什么要写出“假设”？第一：自己记不住；第二：别人不懂。

- **Programs have to be written with two goals in mind:**
 - **Communicating with the computer.** First persuading the compiler that your program is sensible – syntactically correct and type-correct. Then getting the logic right so that it gives the right results at runtime. 代码中蕴含的“设计决策”：给编译器读
 - **Communicating with other people.** Making the program easy to understand, so that when somebody has to fix it, improve it, or adapt it in the future, they can do so. 注释形式的“设计决策”：给自己和别人读

(2) Specification and Contract (of a method)

Specifications (or called Contract)

- Specifications are the linchpin **关键** of teamwork. It's impossible to delegate responsibility for implementing a method without a specification. **没规约，没法写程序；即使写出来，也不知道对错**
- The specification acts as a contract **契约**: the implementer is responsible for meeting the contract, and a client that uses the method can rely on the contract. **程序与客户端之间达成的一致**
 - States method's and caller's responsibilities
 - Defines what it means for implementation to be correct
- Specifications place demands on both parties: when the specification has a precondition, the client has responsibilities too. **Spec给“供需双方”都确定了责任，在调用的时候双方都要遵守**
 - If you pay me this amount on this schedule...
 - I will build a with the following detailed specification
 - Some contracts have remedies for nonperformance

Why specifications?

■ Reality:

- Many of the nastiest bugs in programs arise because of misunderstandings about behavior at the interface between two pieces of code. 很多bug来自于双方之间的误解
- Although every programmer has specifications in mind, not all programmers write them down. As a result, different programmers on a team have *different* specifications in mind. 不写下来，那么不同开发者的理解就可能不同
- When the program fails, it's hard to determine where the error is. 没有规约，难以定位错误

■ Advantages:

- Precise specifications in the code let you apportion blame to code fragments, and can spare you the agony of puzzling over where a fix should go. 精确的规约，有助于区分责任
- Specifications are good for the client of a method because they spare the task of reading code. 客户端无需阅读调用函数的代码，只需理解spec即可

An example of specification

- A method `add()` of a Java class `BigInteger`

Specification from the API documentation :

add

```
public BigInteger add(BigInteger val)
```

Returns a `BigInteger` whose value is `(this + val)` .

Parameters:

`val` - value to be added to this `BigInteger`.

Returns:

`this + val`

Method body from Java 8 source :

```
if (val.signum == 0)
    return this;
if (signum == 0)
    return val;
if (val.signum == signum)
    return new BigInteger(add(mag, val.mag), signum);

int cmp = compareMagnitude(val);
if (cmp == 0)
    return ZERO;
int[] resultMag = (cmp > 0 ? subtract(mag, val.mag)
    : subtract(val.mag, mag));
resultMag = trustedStripLeadingZeroInts(resultMag);

return new BigInteger(resultMag, cmp == signum ? 1 : -1);
```

Specification (contract)

- Specifications are good for the implementer of a method because they give the implementor **freedom to change** the implementation without telling clients. 规约可以隔离“变化”，无需通知客户端
- Specifications can **make code faster**, too. 规约也可以提高代码效率
- The contract acts as a *firewall* between client and implementor.** 规约：扮演“防火墙”角色
 - It shields the client from the details of the *workings* of the unit.
 - It shields the implementor from the details of the *usage* of the unit.
 - This firewall results in *decoupling*, allowing the code of the unit and the code of a client to be changed independently, so long as the changes respect the specification.
 - 解耦，不需了解具体实现

Specification (contract)

- **Agreement between an object and its user**
 - Method signature (type specifications) 输入/输出的数据类型
 - Functionality and correctness expectations 功能和正确性
 - Performance expectations 性能
- **What the method does, not how it does it** 只讲“能做什么”，不讲“怎么实现”
 - Interface (API), not implementation

(3) Behavioral equivalence

Behavioral equivalence (行为等价性)

- To determine **behavioral equivalence**, the question is whether we could substitute one implementation for the other (是否可相互替换).

```
static int findFirst(int[] arr, int val) {  
    for (int i = 0; i < arr.length; i++) {  
        if (arr[i] == val) return i;  
    }  
    return arr.length;  
}  
  
static int findLast(int[] arr, int val) {  
    for (int i = arr.length - 1; i >= 0; i--) {  
        if (arr[i] == val) return i;  
    }  
    return -1;  
}
```

这两个函数是否等价？

行为不同，但对用户来说
“是否等价”？

When **val** is missing,
findFirst returns the
length of **arr** and
findLast returns **-1**;

When **val** appears
twice, **findFirst**
returns the lower index
and **findLast** returns
the higher.

- The notion of equivalence is **in the eye of the client** (站在客户端视角看行为等价性).

Behavioral equivalence (行为等价性)

- To determine **behavioral equivalence**, the question is whether we could substitute one implementation for the other (是否可相互替换).

```
static int findFirst(int[] arr, int val) {  
    for (int i = 0; i < arr.length; i++) {  
        if (arr[i] == val) return i;  
    }  
    return arr.length;  
}  
  
static int findLast(int[] arr, int val) {  
    for (int i = arr.length - 1; i >= 0; i--) {  
        if (arr[i] == val) return i;  
    }  
    return -1;  
}
```

这两个函数是否等价？

行为不同，但对用户来说
“是否等价”？

But when **val** occurs at exactly
one index of the array, the two
methods behave the same.

Whenever they call the
method, they will be passing in
an **arr** with exactly one
element **val**.

- The notion of equivalence is **in the eye of the client** (站在客户端视角看行为等价性).

For such clients, these two
methods are the same.

Behavioral equivalence

- In order to make it possible to substitute one implementation for another, and to know when this is acceptable, we need a specification that states exactly what the client depends on 根据规约判断是否行为等价

```
static int find(int[] arr, int val)
  requires: val occurs exactly once in arr
  effects: returns index i such that arr[i] = val
```

这两个函数符合这个规约，故它们等价。

Classroom Exercises

```
static int findFirst(int[] a, int val) {  
    for (int i = 0; i < a.length; i++) {  
        if (a[i] == val) return i;  
    }  
    return a.length;  
}
```

```
static int findLast(int[] a, int val) {  
    for (int i = a.length - 1; i >= 0; i--) {  
        if (a[i] == val) return i;  
    }  
    return -1;  
}
```

Suppose clients only care about calling the **find** method when they know **val** occurs exactly once in **a**.

In this case, are **findFirst** and **findLast** behaviorally equivalent?

Suppose clients only care that the **find** method should return:

- any index **i** such that **a[i] == val**, if **val** is in **a**
- any integer **j** such that **j** is not a valid array index, otherwise

In this case, are **findFirst** and **findLast** behaviorally equivalent?

Short summary

单纯的看实现代码，并不足以判定不同的implmentation是否是“行为等价的”

需要根据代码的spec（开发者与client之间形成的contract）判定行为等价性

在编写代码之前，需要弄清楚spec如何协商形成、如何撰写

(4) Specification structure: pre-condition and post-condition

Specification Structure

- A specification of a method consists of several clauses:
 - *Precondition* , indicated by the keyword *requires*
 - *Postcondition* , indicated by the keyword *effects*
 - **Exceptional behavior**: what it does if precondition violated
- The **precondition** is an obligation on the client (i.e., the caller of the method). It's a condition over the state in which the method is invoked. 前置条件：对客户端的约束，在使用方法时必须满足的条件
- The **postcondition** is an obligation on the implementer of the method. 后置条件：对开发者的约束，方法结束时必须满足的条件
- If the precondition holds for the invoking state, the method is obliged to obey the postcondition, by returning appropriate values, throwing specified exceptions, modifying or not modifying objects, and so on. 契约：如果前置条件满足了，后置条件必须满足

Specification Structure

- The overall structure is a logical implication: *if the precondition holds when the method is called, then the postcondition must hold when the method completes.* 前置条件满足，则后置条件必须满足。
- If the precondition does *not* hold when the method is called, the implementation is *not* bound by the postcondition.
 - It is free to do anything, including **not terminating, throwing an exception, returning arbitrary results, making arbitrary modifications**, etc.
 - 前置条件不满足，则方法可做任何事情。
 - “你违约在先，我自然不遵守承诺”

Classroom Exercises

```
static int find(int[] arr, int val)
```

requires: `val` occurs exactly once in `arr`

effects: returns index `i` such that `arr[i] = val`

As the implementer of `find`, which are legal?

- if `arr` is empty, return `0`
- if `arr` is empty, throw an `exception`
- if `val` occurs twice in `arr`, throw an `exception`
- if `val` occurs twice in `arr`, set all the values in `arr` to `0`, then throw an `exception`
- if `arr` is not empty but `val` doesn't occur, pick an `index` at random, set it to `val`, and return that `index`
- if `arr[0]` is `val`, continue checking the rest of the array and return the highest `index` where you find `val` (or `0` if you don't find it again)

The client has violated the precondition. As implementers, we are free to do *anything*.

If `arr[0]` is the only occurrence of `val`?
If we do find another `val` in the array?

Classroom Exercises

```
static int find(int[] arr, int val)
```

requires: `val` occurs exactly once in `arr`

effects: returns index `i` such that `arr[i] = val`

- if `arr` is empty, return `0`
- if `arr` is empty, throw an `exception`
- if `val` occurs twice in `arr`, throw an `exception`
- if `val` occurs twice in `arr`, set all the values in `arr` to `0`, then throw an `exception`

As the implementer of `find`, why would you choose to throw an `exception` if precondition is violated?

When our precondition is violated, the client has a bug.

We can make that bug easier to find and fix by **failing fast**, even though we are not obligated to do so.

Specifications in Java

- Java's **static type declarations** *are* effectively part of the precondition and postcondition of a method, a part that is automatically checked and enforced by the compiler. 静态类型声明是一种规约，可据此进行静态类型检查 **static checking**。
- The rest of the contract must be described in a **comment** preceding the method, and generally depends on human beings to check it and guarantee it. 方法前的注释也是一种规约，但需人工判定其是否满足
- Parameters are described by **@param** clauses and results are described by **@return** and **@throws** clauses.
- Put the **preconditions** into **@param** where possible, and **postconditions** into **@return** and **@throws**.

Specifications in Java

```
static int find(int[] arr, int val)
    requires: val occurs exactly once in arr
    effects:  returns index i such that arr[i] = val
```

```
/**
 * Find a value in an array.
 * @param arr array to search, requires that val occurs exactly once
 *           in arr
 * @param val value to search for
 * @return index i such that arr[i] = val
 */
static int find(int[] arr, int val)
```

Recall the code in Lab1

```

/**
 * Determine inside angles of a regular polygon.
 *
 * There is a simple formula for calculating the inside angles of a polygon;
 * you should derive it and use it here.
 *
 * @param sides number of sides, where sides must be > 2
 * @return angle in degrees, where  $0 \leq \text{angle} < 360$ 
 */
public static double calculateRegularPolygonAngle(int sides) {
    throw new RuntimeException("implement me!");
}

/**
 * Given a sequence of points, calculate the Bearing adjustments needed to get from each point
 * to the next.
 *
 * Assumes that the turtle starts at the first point given, facing up (i.e. 0 degrees).
 * For each subsequent point, assumes that the turtle is still facing in the direction it was
 * facing when it moved to the previous point.
 * You should use calculateBearingToPoint() to implement this function.
 *
 * @param xCoords list of x-coordinates (must be same length as yCoords)
 * @param yCoords list of y-coordinates (must be same length as xCoords)
 * @return list of Bearing adjustments between points, of size 0 if (# of points) == 0,
 *         otherwise of size (# of points) - 1
 */
public static List<Double> calculateBearings(List<Integer> xCoords, List<Integer> yCoords) {
    throw new RuntimeException("implement me!");
}

```

Classroom Exercises

Given this spec:

```
static boolean isPalindrome(String word)
  requires: word contains only alphanumeric characters
  effects: returns true if and only if word is a palindrome
```

Here is a flawed attempt to write the spec in Javadoc:

```
/*
 * Check if a word is a palindrome.
 * A palindrome is a sequence of characters
 * that reads the same forwards and backwards.
 * @param String word
 * @requires word contains only alphanumeric characters
 * @effects returns true if and only if word is a palindrome
 * @return boolean
 */
```

Which lines in the Javadoc comment are problematic?

What a specification may talk about

- A specification of a method can talk about the parameters and return value of the method, but it should never talk about local variables of the method or private fields of the method's class.
 - You should consider the implementation invisible to the reader of the spec.
 - In Java, the source code of the method is often unavailable to the reader of your spec, because the Javadoc tool extracts the spec comments from your code and renders them as HTML.

Specifications for mutating methods

- Example 1: a mutating method

```
static boolean addAll(List<T> list1, List<T> list2)
  requires: list1 != list2
  effects:  modifies list1 by adding the elements of list2 to the end of
           it, and returns true if list1 changed as a result of call
```

- Example 2: a mutating method

```
static void sort(List<String> lst)
  requires: nothing
  effects:  puts lst in sorted order, i.e.  $lst[i] \leq lst[j]$ 
           for all  $0 \leq i < j < lst.size()$ 
```

- Example 3: a method that does not mutate its argument

```
static List<String> toLowerCase(List<String> lst)
  requires: nothing
  effects:  returns a new list t where  $t[i] = lst[i].toLowerCase()$ 
```

Specifications for mutating methods

- If the *effects* do not explicitly say that an input can be mutated, then we assume mutation of the input is implicitly disallowed. 除非在后置条件里声明过，否则方法内部不应该改变输入参数
- Virtually all programmers would assume the same thing. Surprise mutations lead to terrible bugs. 应尽量遵循此规则，尽量不设计 **mutating** 的 **spec**，否则就容易引发 bugs。
- **Convention** 程序员之间应达成的默契：除非 **spec** 必须如此，否则不应修改输入参数
 - Mutation is disallowed unless stated otherwise .
 - No mutation of the inputs
- **Mutable objects can make simple specification/contracts very complex** 尽量避免使用 **mutable** 的对象
- **Mutable objects reduce changeability**

Mutable objects make simple contracts complex

- Multiple references to the same mutable object (**aliases** for the object) may mean that multiple places in your program — possibly widely separated — are relying on that object to remain consistent. 程序中可能有很多变量指向同一个可变对象（别名）
- To put it in terms of specifications, contracts can't be enforced in just one place anymore, e.g. between the client of a class and the implementer of a class. 无法强迫类的实现体和客户端不保存可变变量的“别名”
- Contracts involving mutable objects now depend on the good behavior of everyone who has a reference to the mutable object.

不能靠程序员的“道德”，要靠严格的“契约”

Mutable objects make simple contracts complex

- As a symptom of this non-local contract phenomenon, consider the Java collections classes, which are normally documented with very clear contracts on the client and implementer of a class.
 - Try to find where it documents the crucial requirement on the client that you can't modify a collection while you're iterating over it.

remove

```
void remove()
```

Removes from the underlying collection the last element returned by this iterator (optional operation). This method can be called only once per call to `next()`. The behavior of an iterator is unspecified if the underlying collection is modified while the iteration is in progress in any way other than by calling this method.

Throws:

`UnsupportedOperationException` - if the `remove` operation is not supported by this iterator

`IllegalStateException` - if the `next` method has not yet been called, or the `remove` method has already been called after the last call to the `next` method

Mutable objects reduce changeability

- Sharing a mutable object complicates a contract.
- Who's to blame here? 谁为此事负责?
 - Was the client obliged not to modify the object it got back?
 - Was the implementer obliged not to hold on to the object that it returned?

- A possible way of clarifying the spec:

```
public static char[] getMitId(String username) throws NoSuchUserException
    requires: nothing
    effects: returns an array containing the 9-digit MIT identifier of username,
            or throws NoSuchUserException if nobody with username is in MIT's
            database. Caller may never modify the returned array.
```

- How about this spec?
 - It's a lifetime contract! 完全建立在客户端开发者的“良心”之上，不可靠！

Mutable objects reduce changeability

- How about this one?

```
public static char[] getMitId(String username) throws NoSuchUserException
    requires: nothing
    effects: returns a new array containing the 9-digit MIT identifier of username,
              or throws NoSuchUserException if nobody with username is in MIT's
              database.
```

- This spec at least says that the array has to be fresh.
- But does it keep the implementer from holding an alias to that new array?
- Does it keep the implementer from changing that array or reusing it in the future for something else?
- 这回责任又到了开发者这一边的“良心”...都靠不住!

Mutable objects reduce changeability

- How about this one?

```
public static String getMitId(String username) throws NoSuchUserException  
    requires: nothing  
    effects: returns the 9-digit MIT identifier of username, or throws  
            NoSuchUserException if nobody with username is in MIT's database.
```

- The immutable `String` return value provides a *guarantee* that the client and the implementer will never step on each other the way they could with `char` arrays.
- It doesn't depend on a programmer reading the spec comment carefully.
- `String` is *immutable*. Not only that, but this approach (unlike the previous one) gives the implementer the freedom to introduce a cache — a performance improvement. 关键就在于“不可变”，在规约里限定住

(5)* Testing and verifying specifications

Black-box testing

- **Black-box testing:** to check if the tested program **follow the specified specification in an implementation-independent way.**
- **Your test cases should not count on any concrete implemented behavior. Test cases must obey the contract, just like every other client.**
- **An example specification:**

```
static int find(int[] arr, int val)
    requires: val occurs in arr
    effects:  returns index i such that arr[i] = val
```

- **The test case:**

```
int[] array = new int[] { 7, 7, 7 };
assertEquals(0, find(array, 7)); // bad test case: violates the spec
assertEquals(7, array[find(array, 7)]); // correct
```

This test case has assumed a specific implementation that `find` always returns the lowest index.

3 Designing specifications

(1) Classifying specifications

Comparing specifications

- How **deterministic** it is. Does the spec define only a single possible output for a given input, or allow the implementor to choose from a set of legal outputs? 规约的确定性
- How **declarative** it is. Does the spec just characterize *what* the output should be, or does it explicitly say *how* to compute the output? 规约的陈述性
- How **strong** it is. Does the spec have a small set of legal implementations, or a large set? 规约的强度
- “What makes some specifications better than others?”
- 用于判断 “哪个规约更好”

Stronger vs. weaker specs

- How to compare the behaviors of two specifications to decide whether it's safe to replace the old spec with the new spec? 如何比较两个规约，以判断是否可以用一个规约替换另一个？
- 规约的强度 $S_2 \geq S_1$ A specification S_2 is stronger than or equal to a specification S_1 if
 - S_2 's precondition is weaker than or equal to S_1 's 前置条件更弱
 - S_2 's postcondition is stronger than or equal to S_1 's, for the states that satisfy S_1 's precondition. 后置条件更强

Then an implementation that satisfies S_2 can be used to satisfy S_1 as well, and it's safe to replace S_1 with S_2 in program. 就可以用 S_2 替代 S_1

Rules:

spec变强: 更放松的前置条件+更严格的后置条件

- Weaken the precondition*: placing fewer demands on a client will never upset them.
- Strengthen the post-condition*, which means making more promises.

Stronger vs. weaker specs

- Original spec:

```
static int findExactlyOne(int[] a, int val)
  requires: val occurs exactly once in a
  effects: returns index i such that a[i] = val
```

- A stronger spec:

```
static int findOneOrMore,AnyIndex(int[] a, int val)
  requires: val occurs at least once in a
  effects: returns index i such that a[i] = val
```

- A much stronger spec:

```
static int findOneOrMore,FirstIndex(int[] a, int val)
  requires: val occurs at least once in a
  effects: returns lowest index i such that a[i] = val
```

Stronger vs. weaker specs

- How about these two?

```
static int findExactlyOne(int[] a, int val)
  requires: val occurs exactly once in a
  effects:  returns index i such that a[i] = val
```

```
static int findCanBeMissing(int[] a, int val)
  requires: nothing
  effects:  returns index i such that a[i] = val,
           or -1 if no such i
```

前置条件更弱了

在满足`findExactlyOne`的
前置条件的情况下，
该后置条件无变化

Stronger vs. weaker specs

- How about these two?

```
static int findOneOrMore, AnyIndex(int[] a, int val)
  requires: val occurs at least once in a
  effects:  returns index i such that a[i] = val
```

```
static int findCanBeMissing(int[] a, int val)
  requires: nothing
  effects:  returns index i such that a[i] = val,
           or -1 if no such i
```

前置条件更弱了

在满足`findOneOrMore, AnyIndex`的前置条件的情况下，该后置条件无变化

Stronger vs. weaker specs

- How about these two?

```
static int findOneOrMore, FirstIndex(int[] a, int val)
  requires: val occurs at least once in a
  effects:  returns lowest index i such that a[i] = val
```

```
static int findCanBeMissing(int[] a, int val)
  requires: nothing
  effects:  returns index i such that a[i] = val,
            or -1 if no such i
```

前置条件更弱了

在满足`findOneOrMore, FirstIndex`的前置条件的情况下，该后置条件弱化了：没有返回**lowest index**

Exercise

■ When a specification is strengthened:

- Fewer implementations satisfy it
- More implementations satisfy it
- Fewer clients can use it
- More clients can use it
- None of the above

A stronger spec might have a weaker precondition and/or stronger postcondition.

In both cases, the implementor must be more careful; but clients with more varied inputs or more specific needs might now be able to make use of the stronger spec.

越强的规约，意味着implementor的自由度和责任越重，而client的责任越轻。

(2) Diagramming specifications

Diagramming specifications

- Each **point** in this space represents **a method implementation**.

- A **specification** defines a **region** in the space of all possible implementations.
- A given implementation either behaves according to the spec, satisfying the precondition-implies-postcondition contract (it is inside the region), or it does not (outside the region). 某个具体实现，若满足规约，则落在其范围内；否则，在其之外。

Diagramming specifications

- Implementors have the freedom to move around inside the spec, changing their code without fear of upsetting a client. 程序员可以在规约的范围内自由选择实现方式
 - This is crucial in order for the implementor to be able to improve the performance of their algorithm, the clarity of their code, or to change their approach when they discover a bug, etc.
- Clients don't know which implementation they will get. 客户端无需了解具体使用了哪个实现
 - They must respect the spec, but also have the freedom to change how they're using the implementation without fear that it will suddenly break.

Diagramming specifications

- When S_2 is stronger than S_1 , it defines a *smaller* region in this diagram. 更强的规约，表达为更小的区域
- A weaker specification defines a larger region.

Strengthening the postcondition means for implementors: it means they have less freedom, the requirements on their output are stronger 更强的后置条件意味着实现的自由度更低了-
→ 在图中的面积更小

Weakening the precondition means: implementations will have to handle new inputs that were previously excluded by the spec. 更弱的前置条件意味着实现时要处理更多的可能输入，实现的自由度低了 → 面积更小

Diagramming specifications

```
static int findExactlyOne(int[] a, int val)
  requires: val occurs exactly once in a
  effects:  returns index i such that a[i] = val
```

```
static int findOneOrMore,AnyIndex(int[] a, int val)
  requires: val occurs at least once in a
  effects:  returns index i such that a[i] = val
```

```
static int findOneOrMore,FirstIndex(int[] a, int val)
  requires: val occurs at least once in a
  effects:  returns lowest index i such that a[i] = val
```

```
static int findCanBeMissing(int[] a, int val)
  requires: nothing
  effects:  returns index i such that a[i] = val,
           or -1 if no such i
```

ExactlyOne

< OneOrMore, AnyIndex
< OneOrMore, FirstIndex

ExactlyOne

< OneOrMore, AnyIndex
< CanBeMissing

OneOrMore, FirstIndex
CanBeMissing

无法比较

Where should ExactlyOne be?

(3) Designing good specifications

Quality of a specification

- What makes a good method? Designing a method means primarily writing a specification.
- About the form of the specification: it should obviously be succinct, clear, and well-structured, so that it's **EASY TO READ**.
- The content of the specification, however, is harder to prescribe. There are no infallible rules, but there are some useful guidelines.
- 一个好的“方法”设计，并不是你的代码写的多么好，而是你对该方法的spec设计得如何。
 - 一方面：client用着舒服
 - 另一方面：开发者编着舒服

(1) The specification should be coherent (内聚的)

- The spec shouldn't have lots of different cases. Long argument lists, deeply nested if-statements, and boolean flags are all signs of trouble. **Spec描述的功能应单一、简单、易理解**

```
static int sumFind(int[] a, int[] b, int val)
    effects: returns the sum of all indices in arrays a and b at which
             val appears
```

```
public static int LONG_WORD_LENGTH = 5;
public static String longestWord;

/**
 * Update longestWord to be the longest element of words, and print
 * the number of elements with length > LONG_WORD_LENGTH to the console.
 * @param words list to search for long words
 */
public static void countLongWords(List<String> words)
```

Separating those two responsibilities into two different methods will make them simpler (easy to understand) and more useful in other contexts (ready for change).

- In addition to terrible use of global variables and printing instead of returning, the specification is not coherent — it does two different things, counting words and finding the longest word. **该规约做了两件事，所以要分离开形成两个方法。**

(3) The specification should be strong enough

- The spec should give clients a strong enough guarantee in the **general case** — it needs to satisfy their basic requirements.
 - We must use extra care when specifying the **special cases**, to make sure they don't undermine what would otherwise be a useful method.
 - For example, there's no point throwing an exception for a bad argument but allowing arbitrary mutations, because a client won't be able to determine what mutations have actually been made.

```
static void addAll(List<T> list1, List<T> list2)  
    effects: adds the elements of list2 to list1,  
             unless it encounters a null element,  
             at which point it throws a NullPointerException
```

没有充分阐明遇到null
之后参数是否变化

- If a NullPointerException is thrown, the client is left to figure out on their own which elements of list2 actually made it to list1 .
- **太弱的spec, client不放心、不敢用 (因为没有给出足够的承诺)。**
开发者应尽可能考虑各种特殊情况, 在post-condition给出处理措施。

(4) The specification should also be weak enough

```
static File open(String filename)
    effects: opens a file named filename
```

- **This is a bad specification.**

- It lacks important details: is the file opened for reading or writing? Does it already exist or is it created?
- **It's too strong, since there's no way it can guarantee to open a file.**
The process in which it runs may lack permission to open a file, or there might be some problem with the file system beyond the control of the program.

- **Instead, the specification should say something much weaker: it attempts to open a file, and if it succeeds, the file has certain properties.**

- **太强的spec，在很多特殊情况下难以达到，给开发者增加了实现的难度（client当然非常高兴）。**

(5) The specification should use *abstract types*

- Writing our specification with abstract types gives more freedom to both the client and the implementor. 在规约里使用抽象类型，可以给方法的实现体与客户端更大的自由度
- In Java, this often means using an interface type, like Map or Reader, instead of specific implementation types like HashMap or FileReader.
 - Abstract notions like a List or Set
 - Particular implementations like ArrayList or HashSet.

```
static ArrayList<T> reverse(ArrayList<T> list)
    effects: returns a new list which is the reversal of list, i.e.
             newList[i] == list[n-i-1]
             for all  $0 \leq i < n$ , where  $n = \text{list.size}()$ 
```

- This forces the client to pass in an ArrayList, and forces the implementor to return an ArrayList, even if there might be alternative List implementations that they would rather use.

(6) Precondition or postcondition?

- Whether to use a precondition, and if so, whether the method code should attempt to make sure the precondition has been met before proceeding? 是否应该使用前置条件？在方法正式执行之前，是否要检查前置条件已被满足？
- **For programmer:**
 - The most common use of preconditions is to demand a property precisely because it would be hard or expensive for the method to check it.

If to check a condition would make a method unacceptably slow, a precondition is often necessary.

不写Precondition，就要在代码内部check；若代价太大，在规约里加入precondition，把责任交给client

Precondition or postcondition?

- **For user:** A non-trivial precondition inconveniences clients, because they have to ensure that they don't call the method in a bad state (that violates the precondition); if they do, there is no predictable way to recover from the error.
- **So users of methods don't like preconditions.** 客户端不喜欢太强的 **precondition**, 不满足 **precondition** 的输入会导致失败。
 - Thus, Java API classes tend to specify (as a postcondition) that they throw **unchecked exceptions** when arguments are inappropriate. 惯用做法是: 不限定太强的 **precondition**, 而是在 **postcondition** 中抛出异常: 输入不合法
 - This makes it easier to find the bug or incorrect assumption in the caller code that led to passing bad arguments.
 - In general, it's better to **fail fast**, as close as possible to the site of the bug, rather than let bad values propagate through a program far from their original cause. 尽可能在错误的根源处 **fail**, 避免其大规模扩散

Precondition or postcondition?

- The key factors are the cost of the check (in writing and executing code), and the scope of the method. 衡量标准：检查参数合法性的代价多大？
- If it's only called locally in a class, the precondition can be discharged by carefully checking all the sites that call the method.
- If the method is public, and used by other developers, it would be less wise to use a precondition. Instead, like the Java API classes, you should throw an exception.
- 归纳：是否使用前置条件取决于(1) check的代价；(2) 方法的使用范围
 - 如果只在类的内部使用该方法(private)，那么可以不使用前置条件，在使用该方法的各个位置进行check——责任交给内部client；
 - 如果在其他地方使用该方法(public)，那么必须要使用前置条件，若client端不满足则方法抛出异常。

Summary

Summary

- 
- A specification acts as a crucial firewall between the implementor of a procedure and its client.
 - It makes separate development possible: the client is free to write code that uses the procedure without seeing its source code, and the implementor is free to write the code that implements the procedure without knowing how it will be used.

Summary

■ Safe from bugs

- A good specification clearly documents the mutual assumptions that a client and implementor are relying on. Bugs often come from disagreements at the interfaces, and the presence of a specification reduces that.
- Using machine-checked language features in your spec, like static typing and exceptions rather than just a human-readable comment, can reduce bugs still more.

■ Easy to understand

- A short, simple spec is easier to understand than the implementation itself, and saves other people from having to read the code.

■ Ready for change

- Specs establish contracts between different parts of your code, allowing those parts to change independently as long as they continue to satisfy the requirements of the contract.

Summary

- 
- Declarative specifications are the most useful in practice.
 - Preconditions (which weaken the specification) make life harder for the client, but applied judiciously they are a vital tool in the software designer's repertoire, allowing the implementor to make necessary assumptions.

Summary

■ Safe from bugs.

- Without specifications, even the tiniest change to any part of our program could be the tipped domino that knocks the whole thing over.
- Well-structured, coherent specifications minimize misunderstandings and maximize our ability to write correct code with the help of static checking, careful reasoning, testing, and code review.

■ Easy to understand

- A well-written declarative specification means the client doesn't have to read or understand the code.

■ Ready for change

- An appropriately weak specification gives freedom to the implementor, and an appropriately strong specification gives freedom to the client.
- We can even change the specs themselves, without having to revisit every place they're used, as long as we're only strengthening them: weakening preconditions and strengthening postconditions.

The end
